KNMI (1. Sept. – 4. Nov.: visiting scientist at NASA/GSFC)

KNMI - Cabauw (The Netherlands)

(51.971 °N, 4.927 °E)

Cabauw Experimental Site for Atmospheric Research (CESAR*):

- 213m measurement tower
- BSRN measurement site (Cab)
- Atm. boundary layer research
- Gnd. based remote sensing:
 - (Doppler, scanning) Radars**
 - 7 channel scanning MWR
 - MP Lidar (later: Raman Lidar)
 - MFRSR
 - Aeronet site + PFR (expected '07)
 - 2NFOV (planned)
- “Evergreen” surface albedo
- Responsibility: Reinoud Boers

* <http://www.cesar-observatory.nl/>

** not all of them yet operational

Cloud optical depth retrievals by combining solar radiation measurements and RT calculations

Some drawbacks of individual methods

Retrievals using *hemispheric fluxes* affected by broken cloudiness (e.g. Boers et al. 2000)

Retrievals using *2NFOV radiances* degraded by cloud edges and clear-sky contamination (Chiu et al. 2006)

Merge methods:

COUPLED

Chiu et al. 2006: best results for

- broken clouds (cloud cover $\ll 1$)
- low optical depth ($\tau < 30$)
- large spectral contrast in surface albedo (NDVI > 0.4)

COUPLED “retrieval space”

0.0

1.0

$$\lambda_1 = 0.67 \mu\text{m}: \rho_{0.67} = 0.05-0.10$$

$$\lambda_2 = 0.87 \mu\text{m}: \rho_{0.87} = 0.25-0.55$$

2NFOV + MFRSR (“COUPLED”) cloud retrieval method

(Knyazikhin and Marshak, 2005; Barker and Marshak, 2001)

$$I_{\lambda} = I_o + \rho_{\lambda} I_s F_{\lambda}$$

$$\lambda_1 = 0.67 \mu\text{m}$$

$$\lambda_2 = 0.87 \mu\text{m}$$

$$I_s(\tau) = \frac{I_{0.87} - I_{0.67}}{\rho_{0.87} F_{0.87} - \rho_{0.67} F_{0.67}}$$

2 Examples (**stable** and **unstable**)

Oct. 28, 2004;
SZA=52,
 $\rho_{\text{RED}} = 0.13$, $\rho_{\text{NIR}} = 0.28$

Nov. 11, 2004;
SZA=70-75,
 $\rho_{\text{RED}} = 0.17$, $\rho_{\text{NIR}} = 0.36$

A few specific issues related to the REDvsNIR and COUPLED methods

cloud radiative transfer	Cloud optical prop. <u>different</u> in red ($\lambda=670\text{nm}$) and NIR ($\lambda=870\text{nm}$) spectral regions, e.g. phase function
cloud cover and/or cloud inhomogeneity	COUPLED retrieval algorithm based only on plane-parallel RT calculations, i.e. suppressing 3D structure of cloud field
COUPLED retrieval method	The 2-valued retrieval “REDvsNIR” is reduced to a single index retrieval “COUPLED”, i.e. increasing ambiguity

On the way to an improved COUPLED method

How to get stable retrievals under all conditions?

Searching for the extra amount of information: taking a closer look on cloud structures

- 3D view of REDvsNIR: adding fluxes
- Cloud mapping: study of trajectories
- Reviewing the single index retrieval

“low cloud structure”

- clustered REDvsNIR
- clustered I_s/F
- small fluxes

REDvsNIR LUT

F_{red}

TSI

$$\frac{I_s(\tau)}{F_{red}(\tau)}$$

“time” or “Ti”:
decimal UTC

“large flux”

- scattered REDvsNIR
- vertically alligned I_s/F
- large τ (> 30)
- large fluxes
- cloud edge effect

“trajectory”

- scattered REDvsNIR
- vert. and horiz. I_s/F
- constant τ (rel. large)
- variable fluxes
- ? : interesting trajectory

“clear vertical view”

- small REDvsNIR
- vertical I_s/F
- $\tau = 0$ (LUT)
- “not interesting” yet
(no contribution from REDvsNIR)

Concluding remarks

“cloud-trajectory atlas”: tool to study cloud structure in combination with radiance and flux measurements

searching for extra amount of information using fluxes in addition to radiances: new “free parameter” available?

attempt to go from single index retrieval to multiple value retrievals: remove ambiguity
